Meat Products as Functional Foods: A Review

JOSE M. FERNÁNDEZ-GINÉS, JUANA FERNÁNDEZ-LÓPEZ, ESTRELLA SAYAS-BARBERÁ, AND JOSE A. PÉREZ-ALVAREZ

ABSTRACT: Numerous studies have sought to demonstrate the possibility of changing the image of meat and meat products from the traditionally accepted image to one of healthy living thanks to the addition (vegetables, extracts, fibers, and so forth), elimination (fats), and reduction (additives) of different ingredients. This article presents a revision of studies published in recent years on the topic and looks at possible future trends in the sector, analyzing the changes that have occurred in the traditional meat industry as global forces in the agro-food industry direct it more and more to the design and production of functional foods.

Keywords: meat products, functional foods, functional ingredients

Introduction

The trend toward functional foods has led to the publication of several articles describing studies of the effects of including 1 or more ingredients with functional properties in various types of food, within which meat and meat products deserve special attention. The object of including functional ingredients in the case of meat is not only concerned with providing it with certain desirable properties but also an attempt to change its image in these health-conscious days.

The meat industry is 1 of the most important in the world and, whether as a result of consumer demand or because of the ferocious competition in the industry, research into new products is continuous. However, such research and the launch of new products is directed at providing healthy alternatives to what has frequently been accused of causing a variety of pathologies (Jiménez-Colmenero 2000). This unfortunate image derives mainly from the content of fat, saturated fatty acids, and cholesterol and their association with cardiovascular diseases, some types of cancer, obesity, and so forth.

Regarding obesity, it is very important to understand how meat or meat products affects biological and physiological mechanisms of appetite, satiety, and long-term behavior. Meat and meat products show highly satiating characteristics and, in this respect, functional foods could be a food-related solution because these types of products could be designed to be less calorifically dense and while remaining more highly satiating and tasty. In this way, the food industry in general, the meat and related products industry in particular, could contribute to making lives easier and more active.

Meat is associated with cholesterol, and although it is now accepted that the dietary intake of cholesterol has little bearing on plasma cholesterol, for consumers this is another negative influence on meat’s health image (Higgs 2000).

In some cases, the consumer is confused by multiple messages from multiple sources, public skepticism about expert opinion, the public misunderstanding of reports on scientific findings and results, increased media coverage accompanied by recommendations for corporate marketing strategies and health claims, and competing real-life and lifestyle demands. Furthermore, food packaging could also have a very important influence on food intake (MacAulay and Newsome 2004).

The underlying idea behind functional food is to reduce the prevalence of chronic diseases by curbing the consumption of habitually consumed foods. The formulation of foods according to the beneficial effects that their non-nutritional ingredients may have for the consumer has become an area of great interest for large food companies, including the meat sector (Vasconcellos 2001).

Although there is no exact definition of what a functional food is and many consider that it is a concept still under development, among the most widely accepted definition from a European point of view is that mentioned by Robertfroid (Pascal and Collert-Ribbing 1998), namely that “a food may be considered functional if it contains a component (be it nutrient or not) with a selective effect on one or various functions of the organism, whose positive effects justify that it can be regarded as functional (physiological) or even healthy.” A food can be regarded as functional if it is satisfactorily demonstrated to beneficially affect 1 or more target functions in the body, beyond adequate nutritional effects, in a way that is relevant to either improved health or well-being and/or to a reduction in the risk of disease. A functional food must remain food and it must demonstrate its effects in amounts that can normally be expected to be consumed in the diet: it is not a pill or a capsule, but part of the normal food pattern (Dipplock and others 1999). European consumers are more critical and less unconditional than Americans with this type of product because Europeans have recently suffered a sequence of food safety scares (BSE, foot-and-mouth disease, and so forth). Also, among countries, perception is very different; for example in Denmark, consumers are very suspicious of functional foods, which they judge as “unnatural and impure” (Jonas and Beckmann 1998).

As far as meat is concerned, the modifications to which it may be subjected to confer functional properties on it are based on modifications to the feed an animal receives or on postmortem manipulation of the carcass. By the 1st means, the lipid, fatty acid, and vitamin E content can be modified, whereas by the 2nd, fat can be removed by mechanical processes. Regarding meat products, efforts are mainly directed toward their reformulation by modifying the lipid and fatty acid content, and/or by adding a series of functional ingredients (fiber, vegetal proteins, monounsaturated or polyunsaturated fatty acids, vitamins, calcium, phytochemicals, and so forth) (Jimenez-Colmenero and others 2001). Meat and meat products are essential for a balanced diet, although it must also be remembered that they are susceptible to modifications to give them a “healthier” appearance.

The object of this article is to evaluate the effect of adding func-
Functional meat products . . .

Functional modifications in meat and meat products

Meat and meat products are essential in the diet of developed countries. Their principal components, besides water, are proteins and fats, with a substantial contribution of vitamins and minerals of a high degree of bioavailability. Both meat and its associated products can be modified by adding ingredients considered beneficial for health or by eliminating or reducing components that are considered harmful. In this way, a series of foods can be obtained which, without altering their base, are considered “healthy.”

Modification of the fatty acid and cholesterol levels in meat

Meat is a major source of fat in the diet, especially of saturated fatty acids (SFA), which have been implicated in diseases associated with modern life, especially in developed countries. The ratio of n-6:n-3 polyunsaturated fatty acids (PUFA) is also a risk factor in cancers and coronary heart disease, especially the formation of blood clots leading to a heart attack.

Levels of n-3 PUFA in pigs fed a linseed diet produced higher levels of triobarbituric fatty acid reactive substances (TBARS) after conditioning for 10 d followed by simulated retail display for a further 7 d, although the display period had no impact on the sensory characteristics such as muscle color (saturation) (Wood and others 2003).

The selection of breeds and genetic lines within breeds, changes in animal feeding practices, including some feed additives (probiotics, antibiotics, and so forth), and intervention in animal metabolism (anabolic implants, β-agonist, growth hormone, etc.) are the main tools used to achieve a reduction in carcass fat content (Chizzolini and others 1999), although many such practices are not authorized in the European Union.

When Velasco and others (2004) compared unweaned lambs and lambs weaned at 40 d of age, fattened at pasture and slaughtered at 28 kg live weight, to observe the effect on meat quality and fatty acid composition, the weaning status was seen to affect the fatness and quality characteristics of the meat (of lambs raised at pasture) more than the type of feed. A further decrease in the intramuscular fat content would decrease meat quality attributes, especially juiciness and flavor, which are already impaired in some cases (Chizzolini and others 1999). Variations in fatty acid composition have an important effect on firmness or softness of the fat in meat, especially the subcutaneous and intermuscular (carcass) fats but also the intramuscular (marbling) fat.

The effect of fatty acids on meat shelf life is explained by the propensity of unsaturated fatty acids to oxidize, leading to the development of rancidity as display times increases. Changes in fatty acid composition have not been directly linked to changes in myoglobin oxidation and muscle color in many of the pork meat studies reported (Wood and others 2003). In studies of rabbit meat, Dal Bosco and others (2004), confirmed that meat enrichment in n-3 PUFA did not cause any increase in the oxidation level. The α-linolenic acid–vitamin E diet favored the accumulation of long-chain polysaturated n-3 in the meat and improved its oxidative stability and consequently its nutritional value. Enser and others (2000), in studies about feeding linseed to increase the n-3 PUFA in pork meat, confirmed the potential of pig meat to supply valuable n-3 PUFA to the human diet, finding that it may be readily manipulated to increase the concentrations.

Conjugated linoleic acid (CLA) has been recognized as having anticarcinogenic and antioxidative properties in several animal models. Hur and others (2004) reported that the concentration of CLA was significantly increased by the substitution of fat. Storage for 14 d had little effect on the CLA concentration in beef patties. Substituted CLA sources for fat improved the color stability possibly by inhibition of lipid oxidation and oxymioglobin oxidation.

Addition of vegetable oils to meat products

Olive oil is the most monounsaturated vegetable oil. It has a high biological value, and its consumption is related to a decreased risk of heart disease and breast cancer (Pappa and others 2000). Vegetable oils have also been used as partial substitutes of pork backfat in low-fat frankfurters and other types of cooked product giving rise to products with more adequate fatty acid profiles and cholesterol levels than traditional ones (Muguerza and others 2001).

Studies of Pappa and others (2000) concerning the use of olive oil to replace (0% to 100%) pork backfat for the production of low-fat frankfurters, showed that the higher levels of olive oil had the lowest overall acceptability, although color attributes were unaffected.

Muguerza and others (2001) manufactured traditional Spanish sausage, replacing 0% to 30% of pork backfat by pre-emulsified olive oil. The oleic and linoleic acid levels increased and the cholesterol content was reduced, while the sensory characteristics, (texture and color) were comparable with those of commercial products. The results pointed to the possibility of replacing pork backfat with olive oil (up to 25%) to increase the nutritional status.

Ansorena and Astiasarán (2004a) reported that the addition of olive oil to sausages was more effective than using vacuum-storing methods in avoiding lipid oxidation during storage and also increased the monounsaturated fatty acids fraction (MUFA).

Other studies (Muguerza and others 2002) on fermented sausages found that the replacement of 20% pork backfat with olive oil does not affect the weight losses and makes the sausages lighter in color and more yellow. The product has an acceptable odor and taste but unacceptable appearance because of the intensively wrinkled surfaces and the development of casing hardening. The same authors (Muguerza and others 2003b) found that the replacement of 20% pork backfat by olive oil in high and reduced fat Greek sausages led to significant decrease in the oxidation process and significantly increased the MUFA content.

In their studies into “salami” products, Severini and others (2003) found that the partial substitution of pork backfat by extra virgin olive oil did not substantially affect the chemical, physical, and sensory characteristics of the products, with the exception of water activity and firmness. The addition of the extra virgin olive oil, which is rich in unsaturated fatty acids, did not reduce the shelf life in terms of lipid oxidation, probably due to the antioxidant effect of both polyphenols and tocopherols. Sensory analyses did not point to differences from the traditional formulation.

An alternative to using this vegetable oil, which has a high unsaturated fatty acid content and is liquid at room temperature, is to use interesterified vegetable oils (IVOs). These oils can be used as a fat replacer to modify the fatty acid composition of frankfurters and Turkish type salami without any detrimental changes in sensory characteristics. Vural and others (2004) produced frankfurters with IVOs prepared from palm, cottonseed, and olive oils and found that replacing 0% to 30% of pork backfat by pre-emulsified olive oil to sausages was more effective than using vacuum-storing methods in avoiding lipid oxidation during storage and also increased the monounsaturated fatty acids fraction (MUFA).

Other studies (Muguerza and others 2002) on fermented sausages found that the partial substitution of pork backfat by extra virgin olive oil did not substantially affect the chemical, physical, and sensory characteristics of the products, with the exception of water activity and firmness. The addition of the extra virgin olive oil, which is rich in unsaturated fatty acids, did not reduce the shelf life in terms of lipid oxidation, probably due to the antioxidant effect of both polyphenols and tocopherols. Sensory analyses did not point to differences from the traditional formulation.

An alternative to using this vegetable oil, which has a high unsaturated fatty acid content and is liquid at room temperature, is to use interesterified vegetable oils (IVOs). These oils can be used as a fat replacer to modify the fatty acid composition of frankfurters and Turkish type salami without any detrimental changes in sensory characteristics. Vural and others (2004) produced frankfurters with IVOs prepared from palm, cottonseed, and olive oils and found that replacing beef fat (10%) with IVOs (60% to 100%) led to a significant increase in the oleic and linoleic acid content and the PUFA:SFA ratio without any change in appearance, color, texture, flavor, or other sensory characteristics.

Other studies have described the addition of high oleic sunflower oil to low-fat frankfurters as a source of monounsaturated fat. Yilmaz and others (2002) found that the resulting product was...
healthier due to the higher contents of unsaturated and essential fatty acids, without any negative sensory characteristics.

Linseed oil is another source of fat. Ansoarena and Astiasarán (2004b) found that the substitution of pork backfat with linseed oil in the manufacture of dry-fermented sausages decreased the n-6:n-3 ratio (from 14.1 to 2.1) as a consequence of the increase in α-linolenic acid. These authors affirmed that this had a relevant influence on the nutritional quality of the products, without substantially modifying the flavor or oxidation.

Addition of soy

Plant-derived proteins from soybeans have been used in traditional comminuted meat products (30% fat) as meat replacements. Soy proteins (flours, concentrates, and isolates) are more commonly used in processed meat products for their functional properties and relatively low cost compared with lean meat (Chin and others 1999). Soy proteins have been incorporated in these products for their water-binding and fat-binding ability, enhancement of emulsion stability, and increased yields (Chin and others 2000).

Soya protein lowers blood lipid levels compared with animal protein. In 1999, the U.S. Food and Drug Administration approved a health claim that diets low in saturated fat and cholesterol that include 25 g soy protein per day may reduce the risk of heart disease (Sadler 2004). Intact soy (with isoflavones) has a greater effect on reducing low-density lipoprotein (LDL) and total cholesterol concentrations than extracted soy.

Soy isoflavones include compounds such as daidzin, genistin, daidzein, and genistein. However, it has recently been recognized that the isoflavones contained in vegetable proteins may have a detrimental impact on mammals that consume the vegetable protein.

Soy oil also contains approximately 0.2 g plant sterols per 100 g. Plant sterols and plant stanols are associated with lowering plasma LDL cholesterol at intakes of 2 to 3 g/d (Ferrari and Torres 2003; Sadler 2004). Soy has been described as being useful in the prevention and treatment of cancer, osteoporosis, and in the relief of menopausal symptoms (Jiménez-Colmenero and others 2001; Sadler 2004). Intact soy (with isoflavones) has a greater effect on reducing low-density lipoprotein (LDL) and total cholesterol concentrations than extracted soy.

Soy isoflavones include compounds such as daidzin, genistin, daidzein, and genistein. However, it has recently been recognized that the isoflavones contained in vegetable proteins may have a detrimental impact on mammals that consume the vegetable protein.

Soy protein isolate has been added in low-fat bologna, too. Chin and others (2000) characterized this product and concluded that SPI (2%) can be incorporated as fat replacer without any detrimental physiochemical and textural characteristics being noted in the product, except for color values. The addition of SPI did not seem to change the ultrastructure of the meat protein gel matrix, and no interactions were noted with meat proteins. In other studies by the same authors (Chin and others 1999), 4.4% SPI resulted in a softer texture of low-fat bologna and did not affect the other chemical parameters.

Feng and others (2003) incorporated thermally/enzymatically obtained soy protein isolates (2%) in pork frankfurters. They concluded that heat and enzyme-hydrolyzed soy proteins affected texture properties differently, the 1st improving hardness and 2nd reducing hardness, cohesiveness, and breaking strength.

The replacement of pork backfat with soy oil has also been studied. Muguerza and others (2003a) reported that the addition of soy oil did not modify the percentage of water or protein and the pH in fermented sausages. With the addition of pre-emulsified soy oil, cholesterol hardly decreased and oxidation was not modified. Saturated and monounsaturated fatty acids decreased, and polyunsaturated increased due the significant increase in linoleic and α-linolenic acids. In the texture profile analyses, the sensory analysis and color did not show significant differences from commercial products.

Another product, soy protein concentrate mixed with κ-carrageenan (0% to 3%), was investigated in comminuted scalded sausage (Pietrasik and Duda 2000). The addition favorably affected the water-holding capacity and thermal stability of the processed sausages regardless of the fat content. It did not improve the textural parameters, and no significant influence on color parameters was observed.

Addition of natural extracts with antioxidant properties

Lipid oxidation is one of the causes for the deterioration of meat and derivatives because their appearance determines the onset of a large number of undesirable changes in flavor, texture, and nutritional value (Gil and others 2001). The rate of lipid oxidation can be effectively retarded by the use of antioxidants. Synthetic antioxidants were widely used in the meat industry, but consumer concerns over safety and toxicity pressed the food industry to find natural sources (Coronado and others 2002). Natural antioxidants extracted from plants such as rosemary, sage, tea, soybean, citrus peel, sesame seed, olives, carob pod, and grapes can be used as alternatives to the synthetic antioxidants because of their equivalent or greater effect on the inhibition of lipid oxidation (Tang and others 2001). The human intake of green tea decreases total cholesterol, increases the high-density lipoprotein (HDL) fraction, and decreases lipoprotein oxidation (Tang and others 2001; Ferrari and Torres 2003).

The addition of tea catechins to cooked red meat and poultry was studied by Tang and others (2001), who found that addition at 300 mg/kg minced muscle significantly inhibited the pro-oxidative effect of NaCl and controlled lipid oxidation in cooked muscle patties. The high affinity of tea catechins for lipid bilayers of muscle and their radical scavenging abilities may provide a possible mechanism to explain the inhibition of lipid oxidation in cooked muscle food.

The functional properties of raw and cooked pork patties with added irradiated green tea leaf extract was studied by Jo and others (2003). This extract did not have negative effects on the physical and sensory properties and had beneficial biochemical properties; the researchers concluded that irradiated green tea extract powder can be used to add functional properties to pork patties.

Jo and others (2003) added irradiated, freeze-dried green tea to cooked pork patties. The results show that this ingredient had no negative effects on the physical and sensory properties. Lipid oxidation was lower and showed less cooking loss. Also, the patties with added green tea leaf extract had beneficial biochemical properties.

Another extract used in meat products is rosemary, from whose leaves a large number of phenolic compounds with antioxidant activities have been isolated. These include carnosol, carnosic acid, rosmarinol, epirosmarinol, isorosmarinol, rosmarinic acid, rosmaridiphene, and rosmarinquinone (Gil and others 2001; Fernández-López and others 2003). Coronado and others (2002) manufactured wiener sausages with this extract, and no lipid oxidation was observed in the product during long-term frozen storage. Wiener containing rosemary appeared to have slower rates of oxidation than those without antioxidant.

Sodium chloride control

Due to the role of sodium in the development of hypertension in sodium-sensitive individuals, public health and regulatory author-
functional meat products . . .

Oils in the form of n-3 polynsaturated fatty acids occur mainly in cold water fish, whereas n-6 polynsaturated fatty acids come mainly from plants and saturated fatty acids from animal sources. Diets in which cold water fish such as mackerel (Scomber scombrus), salmon (Salmo salar), halibut (Hippoglossus hippoglossus), and trout (Oncorhynchus mykiss) are the main staple are associated with reduced incidence of coronary heart disease but an increased risk of hemorrhage (Halsted 2003).

Epidemiological, clinical, and biochemical studies have provided a great deal of evidence about the protective effect of n-3 polynsaturated fatty acids against some common cancers such as breast and colon cancer, rheumatoid arthritis, inflammatory bowel diseases, and cardiovascular diseases (Hoz and others 2004). Levels of dietary fish oil and dietary antioxidant significantly influence the n-3 fatty acid and cholesterol content of meat lipids (Jeun-Horng and others 2002).

In the studies of Jeun-Horng and others (2002) about the addition of fish oil (2% to 4%) to the diet of chickens used to make chick-
due to its water-binding and fat-binding properties and to improve texture (Cofrades and others 2000). Various types of fiber have been studied alone or combined with other ingredients for formulations of reduced-fat meat products, largely ground and restructured products (Desmond and others 1998; Mansour and Khalil 1999), and meat emulsions (Claus and Hunt 1991; Chang and Carpenter 1997; Grigelmo-Miguel and others 1999).

In studies by Yilmaz (2004), rye bran was used as a fat substitute in the production of meatballs. Rye consumption has been reported to inhibit breast and colon tumor growth in animal models, to lower glucose response in diabetics, and to lower the risk of death from coronary heart disease. The addition of rye bran to meatballs at the levels assayed (5% to 20%) improved their nutritional value and health benefits. The total trans fatty acid content was lower and the ratio of total unsaturated fatty acids to total saturated fatty acids was higher in the samples with added rye bran. The same samples were lighter and yellower than the control samples. The authors concluded that this type of fiber can be used as dietary fiber source.

Another source of fiber is oat. Many of the characteristics of oat fiber such as its water-absorption capacity could potentially benefit products such as fat-free frankfurters and low-fat bologna. Oat products have also achieved a very positive consumer image because of the health benefits that have been associated with their consumption. Oat was added by Steenblock and others (2001) to determine the effects on the quality characteristics of light bologna and fat-free frankfurters. Different types of oat fiber were used, high absorption (HA) or bleached oat (BL) fiber at levels up to 3%. The results indicated that the addition of both types of oat fiber produced greater yields and a lighter red color. Purge was reduced with oat fiber at 3%. Product hardness increased for bologna. It has been reported that oat bran and oat fiber provide the flavor, texture, and mouthfeel of fat in ground beef and pork sausages (García and others 2002).

The components of dietary fiber include fructooligosaccharides (FOS), a generic name for all nondigestible oligosaccharides composed mainly of fructose. The effect of a short-chain FOS on cooked and dry-cured sausages with excellent results (Aleson-Carbonell and others 2003, 2004; Fernández-Ginés and others 2003, 2004; Fernández-López and others 2004). Lemon albedo was added at different concentration (2.5% to 10%) to cooked sausages (Fernández-Ginés and others 2004) and dry-cured sausages (Aleson-Carbonell and others 2003, 2004). The addition of lemon albedo to both sausages had healthy effects due to the presence of active biocompounds, which induced a decrease in residual nitrite levels. Sausages with 2.5% to 7.5% lemon albedo added had sensory properties similar to conventional sausages.

Orange fiber was added at different concentrations (0.5% to 2%) to cooked sausages (bolognas). The results showed that the addition improved the nutritional value, decreased the residual nitrite level, and delayed the oxidation process as determined by TBA values and the red color. Citrus fiber at all concentrations made the products harder and less springy and chewy. All the samples had a similarly good score in the sensory analysis, except the sample with 2% citrus fiber (Fernández-Ginés and others 2003).

García and others (2002) studied the effect of adding cereal and fruit fibers on the sensory properties of reduced-fat, dry-fermented sausages. The cereal (wheat and oat) and fruit (peach, apple, and orange) dietary fibers were added at 1.5% and 3% concentrations. The addition of dietary fiber from cereals and fruits at 1.5% resulted in sausages with a final fiber content, after ripening, of about 2%, which represents an improvement in their nutritional properties and provides an acceptable sensory profile. Higher amounts of fiber (3%) increased the hardness, resulting in products with a lower sensory quality. The best results in this study were obtained with sausages containing 10% pork backfat and 1.5% fruit fiber. The orange fiber provides the best results with sensory properties similar to those of conventional sausage.

Conclusions

Meat and meat products can be modified by adding ingredients considered beneficial for health or by eliminating or reducing components that are considered harmful. The use of these ingredients in meat products offers processors the opportunity to improve the nutritional and health qualities of their products. But sometimes (above all when these ingredients are added at high concentrations) their use results in products with lower sensory and physicochemical quality. The results suggest that many ingredients can be used in the meat industry to add functional properties to meat products, and further research is needed to understand their interactions with meat products constituents and thus to improve their safety in potential industrial applications.
